## **Nova Scotia Mortality Rates For Selected Causes**

**1998 to 2007**

**Prepared by**

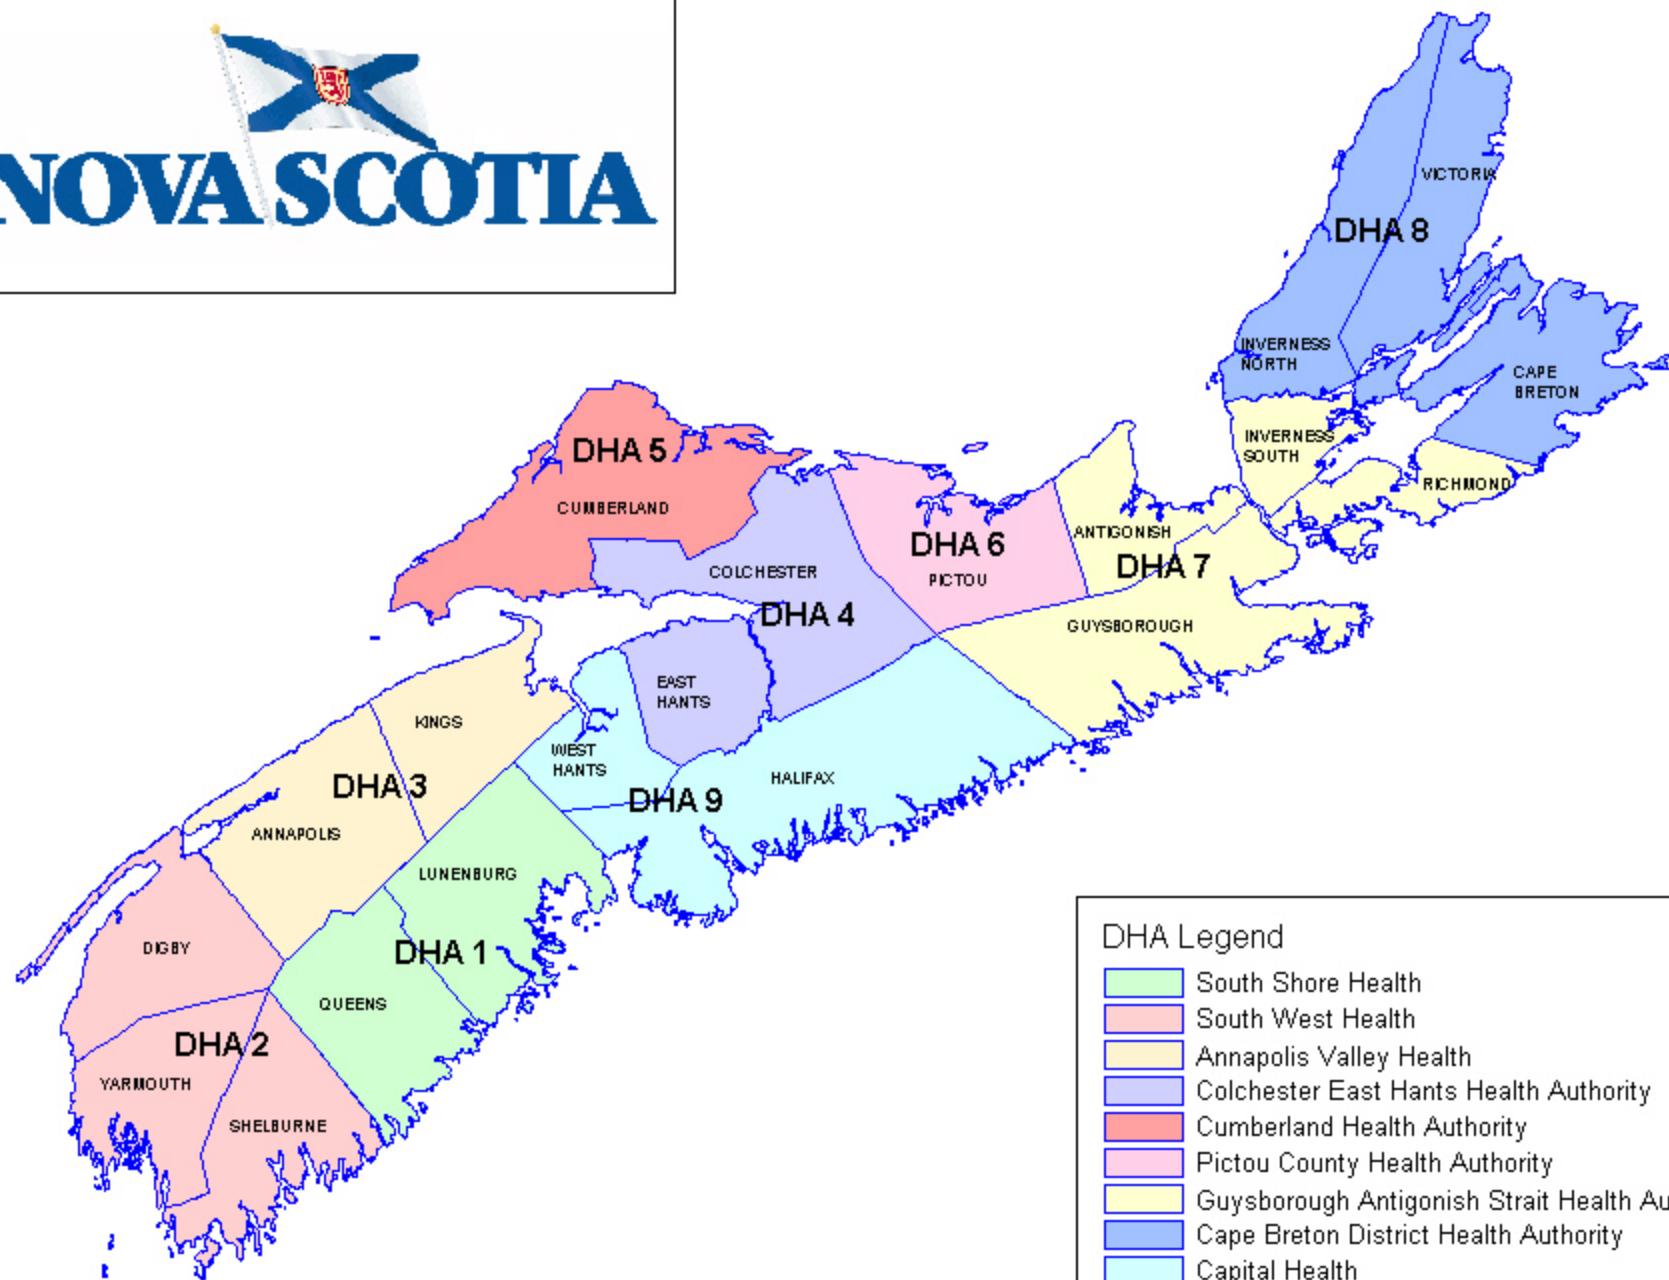

Information Management Services

Nova Scotia Department of Health

This document contains a series of tables and graphs covering the most frequently requested mortality classifications over the period of 1998 to 2007. These tables and graphs are based on age-standardized mortality rates that give the best comparisons across different geographies and times. All Rates are calculated based on District Health Authority of residence, not District Health Authority of death. Nova Scotia residents dying outside the province are not included, nor are deaths of non-residents.

The underlying mortality information is based on the death registration and cause of death databases maintained by Nova Scotia Vital Statistics.

The population estimates used were the most current available from Statistics Canada as of June 2008.

# Rates and Standardization

## Introduction

Different geographic areas and different time periods may lead to dissimilar population structures, *i.e.*, there may be different proportions of young and old people. This can lead to differences in the number of people dying per unit of time and per unit of population. A crude, or unadjusted, rate is calculated by taking the number of deaths in a geographic area in a period of time and dividing by the population (usually taken at the midpoint of the time period) in that geographic area, *e.g.*:

$$\text{Deaths} / \text{Population}$$

To avoid decimals, it is customary to express this as a rate per 100,000 persons:

$$\text{Deaths} / \text{Population} \times 100,000$$

An additional step can be taken to adjust these rates to correct for population differences through a process called standardization.

## Process to Standardize Rates:

- A crude rate for each specific age (and sex<sup>1</sup>) cohort (for example women aged 15 to 19) is divided by the population estimate for the same cohort.
- These crude rates are multiplied by a weight (calculated by dividing the 1991 Canadian population in the specific cohort by the total 1991 population).
- The weighted rates are then added together across all age (and sex) cohorts to produce an age (and sex) standardized mortality rate.

The process of standardizing removes the effects of age (and/or sex) in a population. The resulting age (and sex) standardized rate provides a fairer comparison between geographic areas and different time periods than the crude rate.

---

<sup>1</sup> Rates are generally only adjusted for age, but can be adjusted for sex differences as well. For conditions that only apply to one sex (for example, cancer of the cervix) standardization is done within only the population of that sex.

## Potential Years of Life Lost

### Technical Notes

Potential years of life lost (PYLL) is the number of years lost when a person prematurely dies from any cause (before age 75). PYLL is calculated by taking the median of each age group and subtracting from 75 and then multiplying by the number of deaths in that age group.

$$(75 - (\text{Median of age group})) \times (\# \text{ deaths in age group}) = \text{PYLL}$$

The standardized rate of PYLL per 100,000 population is the calculated PYLL divided by the population, of the given area, under 75 years of age. The standardized rate shows the PYLL for the average person under the age of 75, of people with a given condition, in a given area. A zero simply means that for the given time period there were no deaths attributed to the condition for anyone under the age of 75.

$$(\text{PYLL} / \text{population}) \times 100,000$$
