1 Background and purpose

1.1 Objective

The objective of this review is to update the 2012 ACC report on cervical artery dissection (CAD) and focus on reports on whether techniques like cervical manipulation that may be applied by physiotherapists, chiropractors, or osteopaths is associated with the occurrence of an arterial dissection of the internal carotid or vertebral arteries.

This is a rapid review of the peer-reviewed academic literature that reports the results of a systematic search of the academic literature and critical appraisal of the included papers related to the objective of the report.

1.2 Background

Cervical artery dissection (CAD) is a collective term that includes internal carotid artery dissection (iCAD) and/or vertebral artery dissection (VAD). A dissection is a tear or haematoma in the wall of either the vertebral or internal carotid artery, and can lead to serious events like stroke. The incidence of CAD is relatively low (based on large hospital cohorts it is estimated at 2.6 – 3 / 100,000 individuals a year)¹, with the incidence of iCAD more common (1.7 / 100,000 per year) than VAD (1.0 / 100,000)². The symptoms of a dissection can present as neck or head pain (most common); other clinical features include: visual, speech or balance disturbance; facial palsy; ptosis; paresthesiae in face/tongue or limbs; and limb weakness³. One analysis showed that cervical pain is about twice as common in patients with VAD, while headache at admission is more frequent in patients with iCAD², however it can be difficult to determine the causation of CAD.

The causation of CAD is unclear but has been attributed to both traumatic (where a severe blunt or penetrating trauma has occurred) or spontaneous events⁴. It is described as a multifactorial disease and identified risk factors include cervical trauma, recent infection, hypertension and migraine^{1, 2}. Cervical artery dissection is seen more often younger populations (under 65)^{1, 4}, and is reported to account for 10 – 25% of ischemic strokes in young and middle aged patients⁴. Cohorts of people with CAD and other underlying vascular disorders like: fibromuscular dysplasia; reversible cerebral vasoconstriction syndrome; Ehlers-Danlos syndrome¹; or a family history of CAD⁵ are shown to have increased incidence of CAD compared to people who had CAD but no underlying disorders or family history.

Cervical manipulation is suggested to lead to CAD. This is hard to investigate as the initial symptoms of a CAD can present as musculoskeletal pain for which patients may go to a health professional to treat. So if the CAD was already developed and the patient did not know; the chiropractor / physiotherapist, osteopath or other health professional may perform the manipulation, then when the CAD is diagnosed it is misattributed to the manipulation rather than being a spontaneous event (see Figure 1 below adapted from Church et al, 2016).

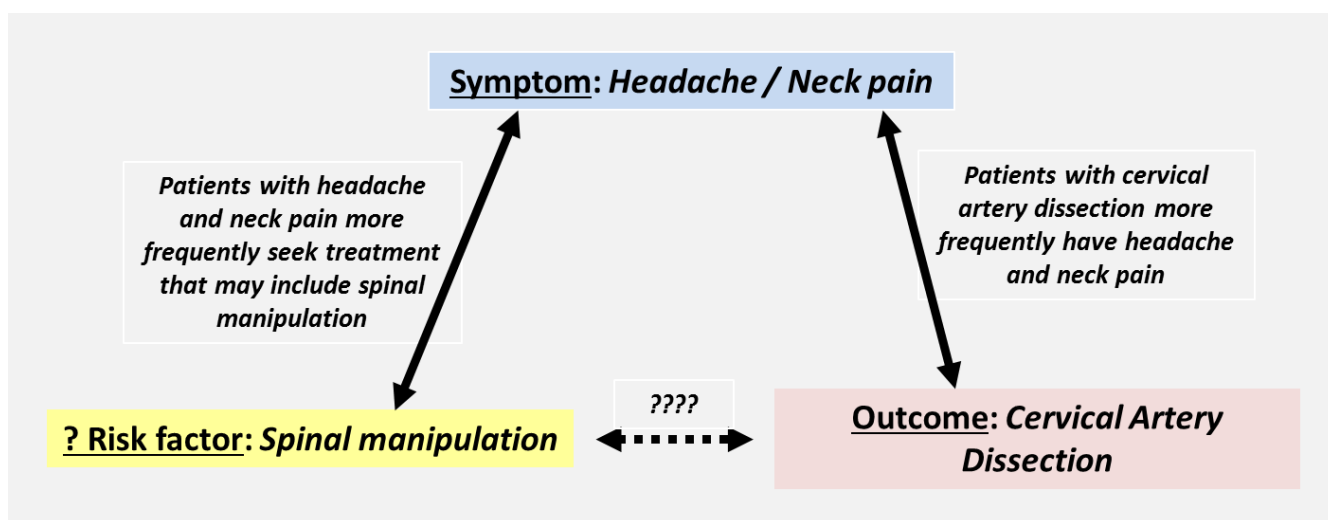

Figure 1. Potential relationship between CAD and symptoms ⁶

1.3 2012 ACC Report on Cervical Artery Dissection

A previous report was completed by the Evidence-based Health group in ACC research in 2012⁷. This report focused on the evidence for causation of CAD by trauma and what degree of trauma is required; and if the symptoms of CAD could be confused with the symptoms of a traumatic event. The summary of this report is quoted as follows:

- “Without major trauma it is unlikely that a CAD is an injury caused by accident;
- It is unlikely that a recent minor event such as lifting or twisting is the cause of a CAD;
- Symptoms of spontaneous CAD (neck, face or head pain in the preceding minutes, hours or days while the intimal split evolves into a dissection) can be misattributed to a CAD caused by trauma.”
- Careful consideration should be given to the history and clinical records, particularly known predisposing factors to the risk of dissection (although these are rare): heritable connective tissue disorders such as Ehlers-Danlos syndrome; arterial anomalies; genetic risk factors; oral contraceptives; smoking; hypertension and respiratory tract infections.

Cervical artery dissection was largely categorised as a traumatic cause by the studies included in this report or reported as a separate category.

Findings specifically related to CAD reported initial symptoms of dissection commonly imitated musculoskeletal pain for which patients typically consult chiropractors; and that some of these patients may have already been developing a CAD before having chiropractic treatment. However the association of CAD and cervical manipulation (high velocity low amplitude thrusts) was not the focus of this review.

2 Methods

2.1 Search Strategy

A standard systematic search was conducted over multiple databases using search terms as described below. This search was aimed to build on information previously reported by ACC⁷.

Two searches were conducted in April 2016 and in November 2016 across the following databases:

- Medline
- Medline Inprocess & ePub Ahead of Print,
- Embase
- Cochrane Library
- Amed
- Ovid Nursing Database

Search terms included: Carotid artery; internal, dissection; carotid artery injuries; vertebral artery dissection; spinal manipulation; manipulation osteopathic; chiropractic physical therapists. (Full search strategy can be found in Appendix 1).

2.2 Inclusion and exclusion criteria

A total of 42 studies were found related to this topic, the inclusion criterion outlined below were used to select studies for the review. Studies selected were systematic reviews published from November 2011 and any studies conducted after May 2013 (see Church et al, 2016).

2.2.1 Inclusion Criteria

- *Study design:* Systematic reviews published after November 2011, reviews of case reports and primary studies that included cohort studies and case control studies published after May 2013

- *Participant*: Human participants with arterial dissection of the carotid or vertebral arteries
- *Intervention*: cervical manipulation / high velocity, low amplitude thrust
- *Type of outcome measures*: radiographic analysis, clinical outcome measures

2.2.2 Exclusion criteria

- Grey literature, conference proceedings
- Arterial dissection of other arteries not in cervical spine
- Animal or laboratory studies
- Single case reports and literature reviews
- Cadaver studies
- Non-English studies

2.3 Level of Evidence

Studies that met the criteria for inclusion in this report were assessed for their methodological quality using the Scottish Intercollegiate Guideline Network (SIGN) level of evidence systemⁱ, as outlined below.

Levels of evidence

1++	High quality meta analyses, systematic reviews of randomized controlled trials (RCTs), or RCTs with a very low risk of bias
1+	Well conducted meta analyses, systematic reviews of RCTs, or RCTs with a low risk of bias
1-	Meta analyses, systematic reviews of RCTs, or RCTs with a high risk of bias
2++	High quality systematic reviews of case-control or cohort studies. High quality case-control or cohort studies with a very low risk of confounding, bias, or chance and a high probability that the relationship is causal
2+	Well conducted case control or cohort studies with a high risk of confounding, bias, or chance and a significant risk that the relationship is not causal
3	Non-analytic studies, e.g. case reports, case series
4	Expert opinion

ⁱ Scottish Intercollegiate Guidelines Network: <http://www.sign.ac.uk/>

3 Results

3.1 Study selection

Five systematic reviews, two retrospective analyses and two reviews of case reports met the inclusion criteria of this report. A brief description of these studies and their level of evidence are outlined below in Tables 2 – 4, further details of the studies can be found in the evidence tables at the end of this document (Appendix 4).

The study designs included in this report, including those analysed in the systematic reviews, are predominantly retrospective analyses of data and case-control studies. This means that information from the primary studies cannot determine if manipulative techniques like high velocity low amplitude thrusts cause cervical artery dissection. However, it can outline which variables or patient characteristics are present when a carotid artery or vertebral artery dissection has occurred, and under what circumstances there are increased odds of CAD occurring.

3.1.1 Systematic reviews (SRs)

A total of five systematic reviews fit the inclusion criteria for this review. There is cross-over (outlined in Appendix 4) of the cohort of primary studies included in the systematic reviews; one review (Dittrich et al, 2007) had been included in all reviews including the review produced in-house by ACC in 2012⁷. The systematic analyses were of moderate to good quality (graded as 2+ to 1-) however the primary studies analysed by the systematic reviews were largely retrospective analyses and case control studies indicating that available primary evidence is of moderate to low quality (graded as 2- to 3).

Table 1. Brief description of included systematic reviews

Study	Overview	Study types	SIGN grade
Church et al, 2016⁶	Evaluate the evidence by performing a systematic review and meta-analysis of published data on chiropractic manipulation and CAD.	N = 6 case-control studies. Five were retrospective analyses and one consisted of face-to-face interviews. <i>Studies were of moderate (n = 2) to low (n = 4) quality, graded using GRADE tool</i>	1-
Gottesman et al, 2012⁸	SR of studies reporting clinical and radiographic data on individuals with vertebral artery dissection	Out of 75 studies included in this review, 16 investigated VAD related to chiropractic treatment. N = 12 of these were retrospective analyses; N = 3 were prospective analyses. <i>Most of these studies were of moderate quality</i>	1-
Chung et al, 2015⁹	SR of studies investigating internal carotid artery dissection after cervical spine manipulation, and whether there are any associations or increased incidence of CAD with manipulation.	Out of 99 identified studies, no studies were found that met the author's pre-determined inclusion criteria.	1-
Haynes et al, 2012¹⁰	Update of SR by Rubenstein et al (2005) and to determine if there is conclusive evidence of a strong association between cervical manipulation and CAD stroke	N = 5 case control studies N = 3 retrospective analyses; N = 1 prospective case-control study; N = 1 Case control and case crossover	2+

		study.	
Wynd et al, 2013¹⁰	To collect and synthesise reports of CAD associated with cervical manipulation	N = 43 studies including case reports and case studies	2+
		Due to study design (case reports) these data are of low quality, however are directly related to this report	

3.1.2 Primary studies

Four primary studies were found that were published after publication of the systematic reviews, or met our inclusion criteria but were not included in the 2012 ACC report⁷. These were mostly retrospective analyses of pre-existing datasets, no studies of higher quality (eg. prospective cohort studies) that met the inclusion criteria were found. One study is an analysis of compensation claims from adverse events arising from chiropractic treatment¹¹ the other is an analysis of a population known to have an arterial dissection in which the demographics were retrospectively examined¹².

Table 2. Brief description of primary studies

Study	Overview	Diagnosis of CAD	Comparisons and demographics included	SIGN grade
Bejot et al, 2014¹³	Retrospective analysis of data from the Cervical Artery Dissections and Ischemic Stroke Patients (CADISP) consortium that compares baseline characteristics and short-term outcomes between patients with single CAD and multiple CAD.	Radiological presentation of dissection (see Appendix 4 for further description) Pure intracranial and iatrogenic dissection after a procedure or CAD due to vascular disorders (eg. Ehlers-Danlos syndrome)	N = 983 participants from the CADISP population compared to N = 659 patients as well as 281 health subjects. Characteristics examined included Hypertension, diabetes mellitus, smoking, obesity, recent trauma, prior manipulation, recent infection and hypercholesterolemia	2-
Jevne et al, 2014¹¹	Retrospective analysis of compensation claims from claims following consultation with chiropractors reported to the Danish Patient Compensation Association and Norwegian System of Compensation from 2004 - 2012	Not described, report included claims that described CAD as the diagnosis	Analysis of N = 300 claims 17 of these for CAD (5.7%); 11 were approved. Costs for financial compensation were high (88.7% of whole complain category were for the CAD cases, which was €2,044,523)	2-
Moon et al, 2016¹²	Retrospective review of endovascular treatment (stent placement or coil occlusion of parent vessel conducted) for cervical dissection from 2006 – 2016.	Population of confirmed CAD patients undergoing stent placement for the dissection	Data extracted on demographics, procedural details, radiographic and angiographic studies. Data on restricted population, N = 93 with carotid artery dissection; N = 23 with vertebral artery dissection that underwent a surgical procedure. N = 67 who had a spontaneous dissection had a chiropractic manipulation within the	2-

			past 30 days	
Thomas et al, 2015³	Cross-sectional case control study comparing participants (<55yrs) with CAD with age and sex-matched comparison group with ischaemic stroke but no CAD.	Radiological diagnosis of CAD, retrospective analyses of medical record reviews and interviews	N = 45 participants (24 with dissection, 21 controls). Review of medical records and detailed structured interview of participants regarding potential risk factors for CAD including minor mechanical trauma to the neck.	2-

3.1.3 Reviews of single case reports

Two reviews that collated the findings of single case reports of adverse events arising from cervical manipulative therapy¹⁴ or ‘massage’ therapy techniques that can include manipulation¹⁵ (n = 177 individual cases) published in the literature were included. Although single case reports represent low quality evidence these reviews were included because they are directly related to this review, there is limited volume published evidence from higher quality study design available and highlight that the large volume of these case reports existing in academic literature could create a publication bias within the literature.

These reviews specifically searched for adverse events related to manipulation. This shows that although a high number of individual cases of manipulation with CAD exist, as these researchers did not search for outcomes related from manipulation in general they many not present a true representation of the population, inferring publication bias. These reviews reported that CAD featured predominantly as an adverse event from manipulation (Table 3) however details of diagnosis were not included.

Table 3. Brief description of reviews of single case reports

Study	Overview	Comparisons and demographics included	SIGN grade
Yin et al, 2014¹⁵	To evaluate all data published between 2003 – 2013 on adverse effects of massage therapy (including manipulation)	Review of single case reports from a number of different countries. Of the 43 case reports included, 10 were adverse events of the vertebral artery.	3+
Puentedura et al, 2012¹⁴	Retrospective analysis of all available case reports in the literature published from 1950 - 2010	N = 134 cases reported across 93 articles. Arterial dissection was the most common adverse event (AE) reported (37.3% of cases; N = 50); Chiropractors involved in the majority of injuries (69.4%; n = 93) following manipulation, followed by osteopathic physicians (8.2%), physical therapists (3.7%)	3+

3.2 Cervical artery dissection occurrence in cases that have had a cervical manipulation

Results outlining findings from three systematic reviews, two primary studies and the two reviews of case reports are presented in Table 4 below. Two SRs did not report data that could be used for statistical analyses so occurrence are not reported in this section^{9, 16}. Some initial observations were that manipulations mainly reported to be performed by a chiropractor, however one study did report manipulation and dissection from other professions as well¹⁷; and that carotid artery dissection was more common than vertebral artery dissection^{12, 19}.

Two SRs show although there is a positive association between CAD and cervical manipulation however there is a high amount of heterogeneity within the sample^{6, 18}. The positive associations were reported across a number of primary studies within the SRs, which indicates increased odds of CAD when a cervical manipulation is performed, however it is noted that the confidence intervals were wide in some of the reports, and that some of these were not statistically significant (see Table 4 below). This could be because where population numbers were reported¹³ the

numbers and percentages of dissection sampled were low, and the number of dissection from manipulation was even lower (Dittrich et al, 2007 and Thomas et al, 2011 reported in the Haynes et al, 2012¹⁰).

Table 4. Reports of manipulation related to cervical artery dissection

Study	Comparison	Finding
Systematic Reviews		
Church et al, 2016	Association between dissection and chiropractic care	<i>Pooled OR for all studies (n = 6 case-control studies)</i> Odds Ratio (OR) 1.74 (95% CI 1.26 – 2.41) – <i>However it should be noted there was significant heterogeneity for this sample (I² 84%)</i> Excluded Class III studies (n = 2 studies) OR 3.17 (95% CI 1.30 – 7.74)
Gottesman et al, 2012	Report of vertebral artery dissection in relation to a chiropractic injury	46 out of 283 patients from across 14 studies reported chiropractic related injuries. Pooled proportion: 0.16 (0.07 – 0.3); pooled SE 0.36
Haynes et al, 2012	Reported results from studies separately	<u>Smith et al, 2003</u> <i>VAD and exposure to manipulation in last 30 days</i> OR(adj) 6.62 (95%CI 1.4 – 30) <u>Dittrich et al, 2007</u> <i>Odds of CAD in included sample</i> OR(adj) 1.5 (95%CI 0.3 – 6.9) <u>Thomas et al, 2011</u> <i>Cases of CAD when exposed to manipulation within 3 weeks of stroke</i> OR (adj) 12.7 (95%CI 1.43 – 112.0) <i>Association with recent head or neck trauma</i> OR(adj) 23.5 (95%CI 5.7 – 96.9)
Primary Studies		
Bejot et al, 2014¹³	Occurrence of multiple CAD with manipulation prior to onset of stroke	Odds of multiple CeAD vs single CeAD after cervical manipulation OR 2.23; 95% CI 1.26 – 3.95) 6% of the single CAD population (n = 49 out of 834) had had a prior cervical manipulation 13.6% of the multiple CAD population (n = 20 out of 149) had had a prior cervical manipulation
Moon et al, 2016	Incidence of manipulation in a population of CAD cases undergoing endovascular stent placement	6 of 67 (9%) of patients with spontaneous dissection had a chiropractic manipulation within the past 30 days
Thomas et al, 2015³	Incidence of cervical manipulation in a population of CAD cases	4 out of 24 had a neck manipulation in the month prior to CAD. In two cases high-velocity thrusts were administered, another case deep massage to the sub occipital region and the final unknown. No participant reported stroke. N = 3 were VAD, N = 1 was iCAD. Not statistically significant (OR 5.2, 95% CI 0.6 - ∞)
Reviews of case reports		
Puentedura et al, 2012¹⁴	Results of case reports in patients with severe adverse events after cervical spine manipulation	Arterial dissection most common adverse event reported (n = 37.3% of cases); 7 of these resulted in death (5 from dissection, 2 from practitioner continuing to perform manipulation) Chiropractors involved in majority of reported injuries (n = 64.9%); followed by osteopathic physicians (8.2%) and physical therapists (3.7%). Temporal relationship of manipulation and adverse event not reported
Yin et al, 2014¹⁵	Results of case reports describing adverse events and if a manipulation was or was not mentioned in the case notes.	10 out of 43 case reports were due to vertebral artery dissection, 5 of these were from a manipulation. Details of the case, temporal relationship and health profession not included.

3.3 Mechanical trauma or neck strain

Thomas et al (2015) reported 17 out of the 24 patients with CAD reported a recent history of minor mechanical trauma (including cervical manipulation)³. The type of trauma or neck strain varied within this group, the most common was activities or sports with jerky head movements.

Other risk factors for single³ and recurring CAD¹³ are presented in Appendix 3 of this document.

3.4 Identification of CAD from compensation claims¹¹

One included primary study was a retrospective analysis of compensation claims in Denmark and Norway from 2004 – 2012¹¹. Different adverse events were investigated with a cohort of claims that undergone chiropractic treatment. CAD made up 17 of 300 (5.7%) of adverse events, 11 of these claims were funded and contributed to 88.7% (€2,044,523) of financial compensation for the whole complaint category from both the Danish and Norwegian compensation organisations. Within this paper although spinal manipulative therapy is discussed it is not stated in the paper that the chiropractic treatment included manipulation.

4 Discussion

4.1 Quality of Evidence

Both secondary and primary research articles were included in this report. These included systematic reviews of case control studies and retrospective analyses of administrative data, primary case-control studies and retrospective analyses as well as reviews of single case studies. There was some overlap in the primary studies that the SRs covered (Appendix 5) and it should be noted that some of the information reported in these reviews was already reported in the previous ACC report⁷. The quality of these data ranged from low (3+) to moderate (2+), however none of these study designs are able to determine if causation of CAD is from cervical manipulation as they only report the prevalence of CAD. It should also be noted that although a positive association was reported across some studies between CAD and manipulation, that the heterogeneity was high and not all studies showed statistical significance; and also that a positive association between manipulation and CAD does not equal causation. To determine if a manipulation leads to dissection a before and after study design with imaging techniques would have to be used, however this would be difficult as CAD occurs after a period of time rather than straight after a manipulation.

Two reviews of low quality data (single case studies) were also included as the content was in alignment with the research question of this review. Both of these reviews reported a combined 177 single cases of CAD after chiropractic treatment that had been reported within the published literature. It should be noted that the higher percentages of CAD (37.3% and 23.2%) reported due to chiropractic treatment are not representative of a general population due to publication bias as the search strategy of these reviews were designed to focus on adverse events from spinal manipulation; not a general search. These reviews were included to highlight the publication bias as the volume of case reports (compared to articles of higher quality study design) in the literature could lead to a perception CAD is associated with chiropractic treatment without understanding the paucity of high quality of study designs available on this topic in general.

Diagnosis of CAD did differ between studies. Radiological diagnosis was mentioned in two primary studies^{3, 13} whereas one other primary study was from claims data that had coded for CAD¹¹, and another was a study on a known CAD population. The most common health profession mentioned with regards to CAD was chiropractic, however it has been stated this could be because chiropractors are more likely to perform this procedure than other professions (physiotherapists, osteopaths) trained in the technique¹¹.

4.1.1 Identification using ICD-9 codes

There has been some contention regarding identification of CAD within a primary article included in two of the SRs^{6, 16}. The primary study used ICD-9 codes to identify cases of CAD who had had a visit to a chiropractor during the 30 days before CAD diagnosis²⁰. It is recently contested that the coding used in this study underestimated the true number of cases²¹. Cai et al 2014 used the same search strategy as Cassidy et al, (2009)²⁰ and added specific dissection ICD codes they had available within their dataset that the database used by Cassidy et al (2009²⁰) did not. They used these codes to identify patients in a Veterans Health Administration (VA) electronic database. They found that the previous study may have underestimated the number of CAD cases in general, and that the ORs calculated for CAD and a visit to the chiropractor within 30 days of diagnosis are likely to be larger. This means that reports using statistics from this study^{6, 16} may underestimate the association between CAD and chiropractic treatment.

4.1.2 Limitation of studies

The main limitation of these studies is that they cannot answer whether cervical dissection is caused by cervical manipulation techniques. One SR did not find any studies that fitted the researchers' pre-determined inclusion criteria regarding the causation of internal carotid artery dissection⁹. However these studies do show, from different primary sources and different populations, that there is a positive association between the occurrence of CAD and cervical manipulation. This means that although there are higher odds of CAD in populations of people receiving cervical spine manipulation, it cannot be determined if the CAD was pre-existing or if the manipulation caused the CAD to occur.

4.1.3 Future study

To determine if cervical manipulation does cause a cervical artery (internal carotid or vertebral artery) dissection a well-designed intervention study (ie. randomised control trial) with high quality imaging would be required before and after the manipulative procedure. These participants would have to be followed up at specific time points in the following weeks to determine if cervical manipulation did lead to an arterial dissection occurring; however the feasibility of this study design may be low due to cost, the resources required and other variables (ie. individual lifestyle or patient risk factors) that may contribute to CAD occurring in individual cases.

4.2 Scientific Statement from the American Heart Association (AHA) / American Stroke Association (ASA)²²

A statement published in 2014 was endorsed by the American Association of Neurological Surgeons and Congress of Neurological Surgeons regarding CAD and cervical manipulative therapy (CMT)²². It is not included with this analysis as it is not a systematic review and no critical appraisal or structured systematic literature search is reported in the methodology so does not meet the pre-determined search criteria. However as the paper is in direct alignment with this report and has undergone extensive AHA internal peer-review the findings are briefly outlined below.

The report discusses four case-control studies that report on the association of stroke and CMT. All four of these studies are included within the primary studies assessed in Church et al (2016), one of the SR's included in this report⁶ (Appendix 4). The main conclusions from these studies in the statement were that CMT is associated with CAD and that while CAD may be of low incidence, there could be serious complications. Also as people with VAD commonly present with neck pain, they can seek therapy for this. This can make it appear that CMT was causal to VAD, when it may have spontaneously occurred.

It was recommended that patients with neck pain and no neurological symptoms after trauma should be informed about potential risks of CMT, and that this CAD should be considered by the health professional before performing CMT.

5 Conclusion

The main limitation of the studies critiqued for this report is that they cannot answer whether cervical dissection is caused by cervical manipulation techniques due to study design. To determine if a manipulation leads to dissection a before and after study design with imaging techniques would have to be used, however this would be difficult as CAD occurs after a period of time rather than straight after a manipulation.

There are some positive associations between the occurrence of CAD and cervical manipulation reported, however it is unable to be determined if the CAD occurred before or after the manipulation was performed.

6.2 Appendix 2. Description of the CADISP Consortium

Two retrospective analyses included in this review sourced data from the CADISP (Cervical Artery Dissections and Ischemic Stroke Patients) consortiumⁱⁱ. Although both studies are likely to be reporting the same individuals both are included in this review as the direction of the analyses is different for each study.

The CADISP consortium is a multinational network based across 19 centres in 9 countries in Europe. The main aim of the project is to increase knowledge of the pathophysiological mechanisms of cervical artery dissection from analysis of data obtained from a large number of patients. Of relevance to this review the CADISP network is also intended to provide data on environmental risk factors and genetic susceptibility to CAD. Patients were recruited consecutively and CAD was matched on age and gender with the ischaemic stroke and healthy groups. They were also strictly matched on geographical origin to avoid stratification bias.

Table 5. Inclusion and exclusion factors for CADISP participants (adapted from Debette et al, 2009²³)

	CAD	Ischaemic stroke	Healthy controls
Inclusion criteria	Radiological presentation of dissection	Recent stroke, no sign of CAD (on ultrasound, MRI or CT)	Individuals from general population without a history of vascular disease (MI, stroke or peripheral artery disease).
Exclusion criteria	Purely intracranial dissection, iatrogenic dissection after a endovascular procedure, and disorders known to cause CAD (eg. vascular Ehlers-Danlos syndrome)	Where CAD cannot be ruled out, endovascular or surgical procedures on coronary, cervical or cerebral arteries. Cardiopathies with a very high embolic risk, arterial vasospasm after subarachnoid haemorrhage. Auto immune or monogenic disease explaining stroke

6.3 Appendix 3: Risk factors associated with CAD

Other risk factors are associated with occurrence of CAD. Below are findings from two primary reports from retrospective analyses^{13 3}.

The study by Thomas et al, 2015³ was a retrospective analysis of data collected using a cross-sectional case-control design. A detailed interview close to time of admission about risk factors was performed. The main findings are presented in Table 7 below. The ORs compare the CAD group with the ischemic stroke group. However none of these are statistically significant, possibly due to very small sample sizes and? it should be noted the risk factors described are similar to those reported in Bejot et al, 2014¹³ in Table 8.

Table 6. Risk factors analysis from Thomas et al, 2015³

Risk factor	VAD (n = 10)	iCAD (n = 14)	Total CAD (n = 24)	Odds Ratio OR(95% CI)
Recent infection	1	4	5	2.5(0.4 – 14.5)
Vascular anomaly	1	3	4	1.9(0.3 – 11.6)
Hypertension	1	4	5	0.8(0.2 – 3.1)
Smoking	3	2	5	0.4(0.09 – 1.3)
Cholesterol	0	1	1	0.6(0.01 -0.5)
Family history	1	0	1	0.9(0.05 – 14.8)
Migraine	4	6	10	6.7(1.3 – 38.0)

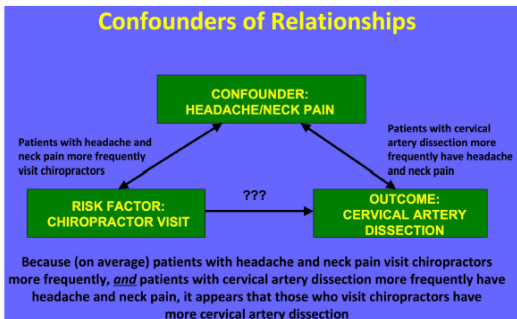

The study by Bejot et al, 2014¹³ reported an analysis of data from the CADISP consortium (for further description see Appendix 7.1). This outlined other participant characteristics that had positive associations with the recurrence of CAD (Table 5). Positive associations for multiple CAD vs single CAD were seen for hypertension, recent infection and recent traumatism (not including cervical manipulation). Findings are presented in Table 7 below.

Table 7. Patient characteristics analysis from Bejot et al, 2014 for multiple vs single CAD

Characteristic	Multiple CeAD (n = 149 (15.2%))	Single CeAD (N=834, 84.8%)	Adjusted analyses (adj for age, sex and country of inclusion) OR (95% CI)
Hypertension (n=249)	43 (29.1%)	206 (25%)	1.53 (1.01-2.31)
Hypercholesterolemia (n = 182)	21 (14.6%)	161(19.7%)	0.75(0.45-1.25)
Diabetes mellitus (n = 21, 2.2%)	5 (3.4%)	16 (1.9%)	1.87(0.66-5.32)
Active smoking (n=269, 27.7%)	31(20.9%)	238(28.9%)	0.63 (0.40-0.99)
Obesity (BMI >31kg/m ²) (n = 68, 7.3%)	11 (7.7%)	57 (7.2%)	1.13(0.58-2.24)
Recent infection n = 187	38 (26%)	149 (18.3%)	1.71(1.12 – 2.61)
Recent traumatism, n = 391 (40.5%)	66 (44.9%)	325(39.7%)	2.23(1.26-3.95)

6.4 Appendix 4: Evidence Tables

6.4.1 Evidence Tables: Systematic Reviews

Systematic Review					
Study	Methodology	Outcomes & results	Quality assessment		Reviewer comments and evidence level
Church et al, 2016 ⁶ <i>Cureus.</i> 8 (2) Study design: Systematic review Research question: To evaluate the evidence by performing a systematic review and meta-analysis of published data on chiropractic manipulation and CAD. Funding No conflicts of interest	Total of 6 studies of included: N = 5 studies include in quantitative synthesis (meta-analysis) N = 6 studies included in qualitative synthesis N = 2 class II studies of case-control design: <ul style="list-style-type: none"> - Smith et al, 2003 (retrospective analyses) - Dittrich et al, 2007 (face-to-face interviews with blinding) N = 4 class III studies of Case control design <ul style="list-style-type: none"> - Rothwell et al, 2001 (retrospective analyses) - Cassidy et al, 2008 (retrospective case control design) - Thomas et al, 2011 (Retrospective analyses of records) - Engelter et al, 2013 (data evaluated from the CADISP study which consists of both retrospective and prospectively collected data) Studies graded using GRADE system Included databases: Medline and Cochrane	 <p>Meta-analysis A meta-analysis was done for the association between dissection and chiropractic care. The pooled ORs for all studies showed a positive association, however the heterogeneity between the studies was high (I^2 84%): OR 1.74 (95% CI 1.26 – 2.41) With Class III studies excluded association still remained however this only included two studies: OR 3.17 (95% CI 1.30 – 7.74) Evidence Grading: Very low due to: <ul style="list-style-type: none"> - Controversial nature of the topic, legal ramifications of results and potential from bias Authors conclusions: </p>	Clearly defined research question Y Two people selected studies and extracted data Y Comprehensive literature search carried out Y Authors clearly state how limited review by publication type Y Included and excluded studies listed N Characteristics of included studies are provided N Scientific quality of included studies assessed and documented Y Scientific quality of included studies assessed appropriately Y Appropriate methods used to combine individual study findings Y Likelihood of publication bias assessed Y Conflicts of interest declared Y Are results of study directly applicable to patient group targeted by guideline? Y	SIGN evidence level: 1- Reviewer comments: Good critique of low quality studies. A comprehensive search was performed however only two databases were searched which may have limited the number of included studies. Univariate analyses for OR used meaning considerations within cohorts that could have an effect on the occurrence of CAD (eg. population demographics, patient history) weren't taken into account for pooled OR	

	Two authors independently reviewed all articles	Found no evidence of a causal link and quality of information is very low. Meta-analysis shows a small association but there is considerable risk of bias and confounding factors in these studies. There is no convincing evidence to support a causal link.

Evidence table: Review of single case studies					
Study	Methodology	Outcomes & results	Quality assessment		Reviewer comments and evidence level
<p>Yin et al, 2014¹⁵</p> <p>Complementary and Alternative Medicine: eCAM. 480956</p> <p>Study design Systematic review</p> <p>Objective To evaluate all published data (between 2003 and 2013) about adverse effects of massage therapy (including manipulation)</p> <p>Funding The work in Austria was supported by the Federal Ministries of</p>	<p>Number of studies: N = 40 articles (138 cases included)</p> <p>These articles varied in content: 33 articles reporting a total of 43 case reports, and 7 reports containing 95 adverse events in case series associated with ‘massage’.</p> <p>Definitions of massage: Massage therapy in this paper included modalities like chiropractic manipulation, neck manipulation and rotation</p> <p>Of these N = 10 (6.5% of all cases) were diagnosed as arterial dissections</p> <p>Databases PubMed incl: MEDLINE, EMBASE, Cochrane Library, CNKI, CQVIP and Wanfang digital databases</p> <p>Inclusion: Only original case reports of complications or adverse events related to massage, manual therapy, and tuina published between January</p>	<p>Main results showed: Of the 43 case reports 10 of the adverse events were dissection of the vertebral artery. Of these 5 were reported as having a manipulation however the details of the case regarding diagnosis of dissection and time of manipulation were not reported.</p> <p>Reports were from a mixture of countries (US, Germany, Japan, Denmark, Spain and China) and clinicians were either not reported, 3 were chiropractors or one was a GP.</p> <p>In the majority of cases, problems were related to spinal manipulations, including rotational movements, which seem to the probable cause of AE’s.</p> <p>Author conclusions: Spinal manipulation in massage has repeatedly been associated with serious adverse events. Clearly they are not totally devoid of risks, but the incidence of such events is low.</p>	Clearly defined research question	N	<p>SIGN evidence level: 3+</p> <p>Reviewer comments: Systematic review of single case reports.</p> <p>Studies included based on content, however there is no clear justification why only case reports were analysed. Quality of the individual case reports was not reported, and details of the cases were missing. Reporting of the included studies has brief and did not go into detail. Although overall findings are aligned with other studies (incidence is low) this review provides little information that helps inform the primary research question regarding causation of cervical dissection.</p>
