Abstract An annotated checklist of fishes of Yonaguni-jima island, Okinawa Prefecture, southern Japan, was compiled mainly from a field survey which was carried out at September 2015 by the authors belonging to five universities, as well as from results from two previous small-scale surveys. Additionally, all registered specimens previously recorded from Yonaguni-jima island were re-examined as much as possible. A total of 603 fish species (104 families) are listed based on the collected specimens during our expedition, museum specimens, literatures and underwater photographs. Each species in the list is stated with citations of literature, registration numbers, sizes, localities around the island, collection methods, collected dates, nomenclatural and taxonomic remarks, and color photographs if available. 334 species (39 families) represent the first reliable records from Yonaguni-jima island on the basis of the collected specimens. The zoogeographical implications of Yonaguni-jima island ichthyofauna are discussed.

Key words: ichthyofauna, Okinawa, Yaeyama Islands, Ryukyu Archipelago, new record, Kuroshio Current.

Introduction

In 1927, Drs. David S. Jordan and Shigeo Tanaka reported four freshwater fish species, *Carassius* sp., *Chanos chanos* (Forsskål, 1775), *Eleotris fusca* (Bloch and Schneider, 1801), and *Kuhlia rupestris* (Lacepède, 1802), from Yonaguni-jima island on the basis of specimens obtained by Mr. H. Kuroiwa (Jordan and Tanaka, 1927). These represent the oldest available fish specimens collected from Yonaguni-jima island. After Jordan and Tanaka (1927), several pieces of literature reported the same four species and *Misgurnus anguillicaudatus* (Cantor, 1842) without deposited specimens (Okinawa Prefecture Experimental Fisheries Station, 1934; Ogawa, 1937; Aoyagi, 1948; Shibata, 1964; Gushiken, 1972; Nakamura, 1974).

No comprehensive reports on fishes from Yonaguni-jima island were published until the 21st-century. Yoshigou (2000) is the first report that focused on the freshwater and brackish ichthyofauna of this island. 63 species of 26 families were reported based on specimens collected in three days in August 1999 by the author. These specimens are currently deposited at Hiwa Museum for Natural History (HMNH). Subsequently, Yoshigou et al. (2001) and Yoshigou and Nakamura (2003) provided the specimen list of HMNH, and the specimens of 35 additional species collected at the tide pools of Yonaguni-jima island were included in this list. However, no comprehensive reports including marine water fishes from Yonaguni-jima island have been published up to the present date, and no integrated surveys have been conducted on or around the island.

To clarify the importance and interesting zoogeographical

features of Yonaguni-jima island, all authors of this study to the exception of the last author T. Uchiyama (who provided a number of underwater photographs) conducted a large-scale expedition at Yonaguni-jima island in 17–26 September 2015 (Fig. 1). In the main survey and two additional small-scale surveys, one by K. Koeda (23–25 July 2013) and one by D. Sasaki (10–16 March 2015), 1,120 specimens of 399 species (211 genera, 72 families) of marine, brackish and freshwater fishes were collected, with 334 representing the first records from the island based on the collected specimens.

This paper provides a list of 603 species of marine, brackish and freshwater fishes (306 genera and 104 families) occurring around Yonaguni-jima island on the basis of collected specimens along with color photographs where available, museum specimens, published literatures, and underwater photographs. Specimens collected from Yonaguni-jima island deposited at HMNH and National Museum of Nature and Science, Tsukuba (NSMT) were re-identified during this study. Finally, the zoogeographical implications of Yonaguni-jima island ichthyofauna are discussed.

Yonaguni-jima island

Yonaguni-jima island is located at 24°27'N, 122°57'E (Fig. 2A), ca. 70 km and ca. 120 km west from Iriomote-jima (Fig. 2B) and Ishigaki-jima (Fig. 2C) islands, respectively. This small island belongs to the Yaeyama Islands, and is the westernmost island in Japan. The distance between Yonaguni-jima island and Taiwan is only ca. 110 km, and the mountains of

Taiwan are sometimes visible from westernmost Cape Irizaki on Yonaguni-jima island. The shape of island is elliptical, with an area of ca. 28 km² and 28 km of coastline (Fujimoto, 1972). Most of the coast-line of the island consists of sheer rocky cliffs. Thus, in-reef environments such as shallow waters, coral reefs, and sandy beaches are extremely limited (Fig. 3). Hikawa Bay on the southern side of the island (Fig. 3, number 23; Table 1) is the only large in-reef environment of the island. Two fishing ports, Kubura and Sonai, located on the north coast, compose inner bay environments with muddy bottoms. Two small rivers, the Tabaru and Kubura rivers, run into the north coast. Tabaru River starts from a spring, ca. 1.5 km upstream from the mouth, and consists of ca. 600 m of freshwater and mangroves estuary (Yoshigou, 2000). Kubura River starts from a brackish lake, Kubura-mit, which is located ca. 300 m from the mouth of the river. Although such monotonous environments in coastal areas of an island generally result in a decrease in fish species diversity, Yonaguni-jima island has a relatively high diversity as the island faces the warm and strong Kuroshio Current, which brings tropical fishes from the south.

The Kuroshio Current flows from east of the Philippines to the Pacific coast of southern Japan, via the channel between Taiwan and Yonaguni-jima island [Fig. 1 in Motomura et al. (2010)]. Yonaguni-jima island is sometimes surrounded by the Kuroshio Current, and thus the current of the sea can become furiously strong, and the sea conditions around the island are often unsettled. For this reason, Yonaguni-jima island was called “Donan” in traditional Okinawan dialect, which means “difficult to pass to the island”.

Materials and methods

Fishes were collected by using SCUBA diving or snorkeling with hand nets and spears, line-fishing from coast or boats, and gill nets, cast nets, fishing lights, and tube traps in shallow waters. Only a handful of specimens were purchased at the fish landing port at Yonaguni-jima island. Curatorial procedures for collected specimens followed Motomura and Ishikawa (2013).

The systematic arrangement of families generally follows Nelson (2006). Scientific names and taxonomical attributions generally follow Nakabo (2013) with some modifications by recent published or unpublished taxonomic studies. Authorship and published year follow Eschmeyer et al. (2016). Species in families are arranged in alphabetical order by species name. Standard Japanese names generally follow Nakabo (2013), and are arranged in Japanese “katakana”. Local names in Yonaguni-jima island generally follow Ikema (2003), and are arranged in Japanese “hiragana” if available. Each species record in the list was compiled from voucher specimens and literature sources. Each voucher specimen in the list includes registration number, number of specimens registered if more than one, standard length [abbreviated as SL; total length (TL) are used in the order Anguilliformes], sex, locality on Yonaguni-jima island (Fig. 3, Table 1), collection method, and collection date. The list of specimens used in previous

Remarks. Jordan and Tanaka (1927), Kuroiwa (1927), Okinawa Prefecture Experimental Fisheries Station (1934), and Aoyagi (1948) reported *Carassius auratus* (Linnaeus, 1758) (Japanese name “Funa”) from Yonaguni-jima island. Fujimoto (1972) noted that “Funa” and “Hibuna” (= *C. auratus* or *Carassius* sp.) occurred in Yonaguni-jima island but he did not identify it as a species level. Kouchi (1991) recorded “Ginbuna” from Yonaguni-jima island. Yoshigou (2000) did not collect *Carassius* sp. but he speculated that *C. auratus* in those reports are misidentification of “Ginbuna” (*Carassius auratus langsdorffii* Temminck and Schlegel, 1846). Takada et al. (2010) analyzed mitochondrial DNA of *Carrassius auratus*-complex collected from China, Taiwan, and Japan, and they reported three generic clades were found from Ryukyu Islands including Ishigaki-jima island. Each clade can be considered as a species or subspecies level, but the taxonomic decision has not been concluded. Although Hosoya (2013) applied *Carassius* sp. for “Ginbuna” without detail explanation, we provisionally follow Hosoya (2013) on the scientific name of “Ginbuna” in our species list, and exclude *C. auratus*.

It was rediscovered in 2007 by Dr. J. Nakajima and his research team (J. Nakajima, pers. comm.). After that the population of *M. anguillicaudatus* has been monitored by them and it is also collected during our survey.

Remarks. Fujimoto (1972) reported “Medaka” [=*Oryzias latipes* (Temminck and Schlegel, 1846)] from Yonaguni-jima island without specimens or photos. However, no later publications mentioned about his report (e.g., Senou, 2013). Nonetheless, this species known as not be distributed in the Yaeyama Islands (Kuroiwa, 1927; Senou, 2013), and can consider that was misidentification of *Gambusia affinis* which is also collected during our survey. From 1924, the species was widely introduced to Yaeyama Islands to exterminate malarial mosquito (Takahara et al., 1997). It was firstly introduced to Yonaguni-jima island in 1934 at first from Ishigaki-jima island (Takahara et al., 1997). Therefore, it is considered that it is widely and numerously distributed in Yonaguni-jima island when the survey by Fujimoto (1972). *Gambusia affinis* is sometime confused with *Oryzias* spp. because of the similar size and the body shape (Saitoh and Uchiyama, 2015). Consequently, we exclude it from our list.

Discussion

In this study, 603 fish species (306 genera and 104 families) were confirmed to occur around Yonaguni-jima island based on the examination of 1,314 specimens, 146 photographs, and previous literature. 334 species and 78 species are representing the first records from the island based on collected specimens and photographs, respectively. 1,120 specimens of 399 species (211 genera, 72 families) of marine, brackish and freshwater fishes were collected during our expedition at Yonaguni-jima island, with 299 species representing the first records from the island. Two species, *Cypo zaps* (Pseudochromidae) and *Opistognathus variabilis* (Opistognathidae), were collected for the first time from Japanese waters in our expedition. These have been separately reported with morphological descriptions and taxonomic information (Hibino et al., 2016; Yoshida et al., in press).

The most speciose families of fishes in marine, brackish, and freshwater of Yonaguni-jima island are listed in Table 2. Consequently, a total of 94 species of 33 families and 28 species of 12 families were confirmed from brackish and fresh waters of Yonaguni-jima island in the present study, respectively (Table 2). It is dramatically fewer than the adjacent islands [290 in Ishigaki-jima and 493 in Iriomote-jima islands (Yoshigou, 2014)] because of fewer and smaller rivers on Yonguni-jima island. As stated above, Yoshigou (2000) recorded 63 fresh and brackish waters species (26 families) from Yonaguni-jima island in three days survey including 50 species (22 families) from Tabaru River. However, despite focused effort collecting fresh and brackish water specimens survey in our expedition, only 27 species of 12 families were collected from the Tabaru River. In 1999, the tideland of Tabaru River in the mangrove area had a highly speciose environment with some numerous small gobies, e.g., *Acentrogobius janthinopterus* (Bleeker, 1853) and *Callogobius tanegasimae* (Snyder, 1908) (Mr. H.

Yoshigou, pers. comm.). In contrast, this area was a very poor environment in the present survey in September 2015, and there were few macro-benthos or gobies [*Eleotris acanthopoma* Bleeker, 1853, *Pandaka trimaculata* Akihito and Meguro, 1975, *Periophthalmus argentilineatus* (Bleeker, 1854), and *Pseudogobius* sp.]. The sluice gate of Tabaru River and its mouth area were repaired and modified after the survey in 1999 by Yoshigou (2000). From personal communications with Mr. H. Yoshigou, it is inferred that the salinity level of Tabaru River became extremely much lower than in 1999 due to the repair work. These results indicate environmental deterioration has been occurred in the Tabaru River.

The presence or absence of inshore fishes represents biogeographical features more clearly than the presence or absence of deepwater fishes, which usually have a broader distribution (sometimes even circumglobal). In total, 565 marine fish species of 95 families are recorded from Yonaguni-jima island. The top 15 marine fish families comprise 64% of the total ichthyofauna; in those, Labridae (47 species), Pomacentridae (39 species), and Gobiidae (37 species) are the dominant families, with a total of 123 species representing more than 20% of total ichthyofauna. In the Ryukyu Archipelago, Senou et al. (2006; 2007), Watai et al. (2009), and Motomura et al. (2010) reported ichthyofaunal checklists which mainly focused on marine fishes of the Miyako Group (Fig. 2D), Ie-jima island (Fig. 2F), Tokashiki-jima island (Fig. 2E), and Yaku-shima island (Fig. 2H), respectively, and ranked the most speciose families. Additionally, field guides of Iou-jima and Take-shima islands (Fig. 2I), and Yoron-jima island (Fig. 2G) were published by Motomura et al. (2013) and Motomura and Matsuura (2014), respectively, on the basis of collected specimens and underwater photographs. Although, some reports include freshwater and brackish water fish in their rank, their results are herein compared at Table 3. Our expedition was carried

out over only 20 days (10 days for main survey at September 2015), and was obviously shorter than the other previous research (Motomura et al., 2010, 2013; Motomura and Matsuura, 2014). However, the number of collected species has no large difference among those reports. The list of marine fishes of Yonaguni-jima island does show some differences from other reports. Gobiidae which was ranked as 1st in most of other islands, are ranked as 3rd, and Labridae and Pomacentridae are 1st and 2nd, respectively. In addition, the percentages of these three families are generally lower than at other islands. Chaetodontidae, Serranidae, and Acanthuridae are ranked 4th to 6th with small differences in Yonaguni-jima island, but those were lower (Chaetodontidae: 5th to 7th; Serranidae: 4th to 10th; Acanthuridae: 7th to 11th) in other islands. Lutjanidae ranked 7th in Yonaguni-jima island, higher

(12th to 18th) than the other islands. Balistidae (11th) is also a higher rank than at the other islands. On the other hand, the ranks of Apogonidae (8th) and Blenniidae (11th) in Yonaguni-jima island are obviously lower than those of the other islands (Apogonidae: 4th to 6th; Blenniidae: 4th to 8th). The present results from Yonaguni-jima island can be characterized by high species diversity in middle-sized swimming taxa (e.g. Chaetodontidae, Acanthuridae, Lutjanidae, and Balistidae), and low species diversity in small-sized benthic taxa (e.g. Gobiidae, Apogonidae and Blenniidae). Based on our results of the unusual species composition, it is speculated that the ichthyofauna of Yonaguni-jima island is influenced by the combination of environmental factors, such as few and small rivers, narrow shallow reef areas with few inner bays, and especially strong water currents surrounding the island.

Acknowledgments

We are especially grateful to the supervisors of the authors, H. Motomura (KAUM), S. Kimura (FRLM), Y. Sakai (Hiroshima University), Y. Iwatsuki (MUFS), and K. Tachihara (University of the Ryukyus) for their kindness and support throughout the whole study. We deeply thank H. Yoshigou (Chugai Technos Co., Ltd.) for providing environmental information of Tabaru River and photographs of fresh specimens collected at Yonaguni-jima island. We also thank S. Takenishi (Yonaguni Fishery Association), H. Muramoto (Education Board of Yonaguni Town), Y. Shichijo and H. Nakamura (Fisheries Division of Okinawa Prefecture), and T. Yoshino (URM) for giving advice and support for our expedition. We greatly appreciate Y. Nishioka (Okinawa), many other anglers in Yonaguni-jima island, and the staff of Diving Service MARLIN for providing a large number of valuable fish specimens and underwater photographs, and J. Nakajima (Fukuoka Institute of Health and Environmental Sciences) for providing information on *M. anguillicaudatus*. We also sincerely thank K. Matsuura and E. Katayama (NSMT), H. Senou (Kanagawa Prefectural Museum of Natural History), and H. Iwatsubo (Kagoshima Museum of Aquatic Biodiversity) for providing identifications of Balistidae, Trichonotidae, Gobiidae and Mugilidae, and Pomacentridae, respectively. We also thank G. Shinohara and M. Nakae (NSMT), S. Nakamura (HMNH), K. Sato, S. Oka, and K. Miyamoto (Okinawa Cyurashima Fundation) for their support in examining deposited specimens. We are deeply indebted to T. Shimose (Seikai National Fisheris Reseach Institute, Fisheries Research Agency), F. Ziadi-Künzli (University of the Ryukyus), students and volunteers of KAUM, especially S. Koeda, B. Jeong, S. Tashiro, H. Hata, and Y. Fukui, for curatorial assistance, providing references, and processing specimen photographs. J.D. Reimer (University of the Ryukyus) improved the English of the manuscript. This study was supported in part by a Grant-in-Aid from the Japan Society for the Promotion of Science for JSPS Fellows (PD: 26-477; DC1: 23-2553) (DC2: 15J02820) to the first author and second author, respectively, and the Sasakawa Fund for Scientific Research to the fourth and fifth authors.
